DomeSim and The 40 Hour Cabin: the project so far

Written 14 October 2026. Every figure on this page is counted or computed by the project's own code that day.

What it is. One person's open-source project to make a small, owned home cheap enough that the house stops eating the household. It has two halves that keep each other honest: a *method* for framing round buildings from logs split lengthwise with one chainsaw, and the *software* that solves, prices, films and writes about that method, so that no number anywhere is typed by hand. It is built by Donovan Zeanah, a U.S. Navy veteran, in the open at github.com/dkzeanah/DomeSimulator.

The method. A two-frequency geodesic dome, 19.42 ft across with 277 sq ft of floor, framed from 120 wedges split from logs and assembled as 40 flat panels on one jig, joined in pinwheels so nothing meets at a corner; 37.5 hours to frame by the project's clock, about 67 for the whole building. Splitting keeps 89% of a log against 57% sawn into two-by-fours. The product built on it is the *stem cell*: one standard body with a utility core ($1,890), snap-in panels, seams that double as channels for rain, wire and air, and a silicone-soaked cotton skin, listing at $12,036 ($43.45 a sq ft against $217 for a new site-built house), in 15 fit-outs. It stands on a serviced pad: own the building, rent the ground. The same wedges now frame a zome too: 36 panels, every cut one 22.5° bevel, 9 log sections against the dome's 15.

The software. 610 Python files, about 337,364 lines. At its centre is the raw-wedge solver and its 3-D world, which cuts and joins every member; around it, the Dome Creator, the Triangle Infill calculator, the new Wedge Zome world (with rulers, a six-foot person and a click-to-measure readout), cost models for the stem cell, the campaign and a park of pads, the seam-climate controller, the cell wall, the sky-web build, a CNC shop, a book engine whose manuscripts carry live number tokens, a film pipeline that renders narrated lessons in a shared 3-D "Cabin World" in the owner's own synthesised voice and resumes after a crash, a website (zeanahlab.com) that sells the book and runs a dome network, and a recorder that logs how the work gets done.

What has been written. *The 40 Hour Cabin: Complete Edition* (83 chapters in 15 parts, sold on the site with the code); *The 40 Hour Cabin: 2V Geodesic Dome Wedge Method*, the Amazon paperback (55 chapters); the *Master Edition*, a 853-page reader's proof that tells the whole idea in 6 rungs from a bedtime story to published experiments, across 12 threads, with both books bound in; *'Square' on Demand* (32 pages), on two wedges paired into a 3.87 in square only where a square is needed; a title page for *Zome Zoomer*; and *Domology*, a three-in-one book in progress.

What has been filmed. 85 films registered and 34 rendered; 211 video files in deliverables, counting phone cuts and teasers, and 109 PDFs. The newest, *Beyond the Dome*, takes the method past the dome: square on demand, shims, roof pitches, octagons, joints and the zome.

The ask, and who it is for. A grant one-pager and a sheet of efficiency charts ask for $100,650, the sum of costed lines: prove it, then make it repeatable. It is built by a veteran for veterans – 32,882 were homeless on one night in January 2024 (HUD) – to sit beside the programs that already house them.

What is proved, and what is not. Measured: the splitting rate (30 wedges per 4-hour session), strut weights (15-22 kg) and a full-size prototype frame. Modelled: cost, energy, rain, recovery. Not yet: an engineer's rating, an instrumented year of weather, the moulded shell and its tooling. And the numbers that argue back stay on the page – paired squares keep only 53% of a log, less than the mill.
